### QUESTION 1 - Measuring volatile contents in bubble-bearing melt inclusions

In this notebook you will learn how to analyze melt inclusion (MI) data in order to estimate the depths of entrapment of each MI using compositional information. To do so, we will be using geochemical and solubility modeling since the solubility of  $H_2O$  and  $CO_2$  are directly controlled by the pressure (and thus depth) at which the MI was entrapped in its host crystal. For this exercise we have provided an excel spreadsheet containing some of the data from Wieser et al. (2021) who performed measurements on the compositions of melt and vapor phases in a set of crystals from Kilauea volcano, Hawaii. The same data is provided in an accompanying csv file. The presence of bubbles within MI can be due to diffusion of  $CO_2$  out of the glassy portion of the MI at high temperature. Raman spectroscopy can be used to measure the abundance of  $CO_2$  within these bubbles.

### EXERCISE INSTRUCTIONS AND QUESTIONS

#### You are provided with the following information:

- 1. Glass inclusion compositions (corrected for post-entrapment crystallization), including H<sub>2</sub>O and CO<sub>2</sub> concentrations;
- 2. The volumetric size of any bubble present in the inclusion (vapor bubble vol%);
- 3. The  $CO_2$  Fermi diad separation,  $\Delta(cm^{-1})$  from Raman analyses.
- Download the dataset for Kilauea Volcano melt and fluid inclusions at: <u>Link</u>
   (<a href="https://github.com/kaylai/EoV">https://github.com/kaylai/EoV</a> CH2 2/blob/main/exercises/Exercise1 Kilauea/Wieser Kilauea Data.xlsx)
- The answer key to this notebook is in the form of a CSV file that should match the file created at the end of this notebok and can be downloaded here: <u>Link</u>
   (<a href="https://github.com/kaylai/EoV\_CH2-">https://github.com/kaylai/EoV\_CH2-</a>

   2/blob/main/exercises/Exercise1 Kilauea/Kilauea Exercise KEY.csv)

#### **Assignment:**

- Calculate saturation pressures for the melt inclusions based on the H<sub>2</sub>O and CO<sub>2</sub> concentrations of the glasses, using VESIcal.
- Calculate the density of the melt as represented by the glass compositions using DensityX (lacovino & Till, 2019).
- 3. Calculate the density of the CO<sub>2</sub> in the bubbles using the equation to convert the diad separation into density. Here we will run through a simplified calculation using empiracle regressions from Fall et al. (2011) and Wieser and DeVitre (2024). Fall et al. (2011) provides an equation that only requires the Fermi diad separation value as an input:
  - $\rho = -0.030314551\Delta^3 + 9.432834797\Delta^2 977.9384933\Delta + 33780.38242$
  - Where ρ is the density and Δ is the separation distance between the two peaks of the Fermi diad in cm<sup>-1</sup>. The python3 program DiadFit (Wieser and DeVitre, 2024) (https://www.jvolcanica.org/ojs/index.php/volcanica/article/view/252) can be used to process Raman spectroscopy data and provide a fit to measured peaks and correct for instrument drift. Wieser and DeVitre (2024) provided the necessary values of correction factor, regression gradient, and regression intercept that allow us to calculate CO<sub>2</sub> densities with their corrections. We'll create a second function to solve:
  - $\rho = \Delta \times Corr \times Regr_{gradient} \times Regr_{intercept}$
  - Where  $\rho$  is again the density,  $\Delta$  is again the Fermi diad separation, Corr is the correction factor,  $Regr_{gradient}$  is the gradient of the regression through their data, and  $Regr_{intercept}$  is the intercept of the regression through their data.
- 4. Calculate the concentration of CO<sub>2</sub> in the bubble (in ppm) using:

• 
$$[CO_2]^{VB} = 10^4 \times \frac{\rho_{CO_2} V_{VB}}{\rho_{melt} V_{melt}}$$

- where  $V_{VB}$  and  $V_{melt}$  are the volume of the vapor bubble and the melt phase of the inclusion, respectively, and  $\rho_{melt}$  is the density of the silicate melt.
- 5. Calculate the total amount of CO<sub>2</sub> in the inclusion (in ppm):

• 
$$[CO_2]^{Tot} = [CO_2]^{VB} + [CO_2]^{melt}$$

- Use the total volatile contents of the inclusions to calculate saturation pressures using VESIcal.
- 7. Compare these pressures to those you calculated in 1. What can you conclude about the importance of analyzing bubbles in melt inclusions?

#### Performing the calculations

For each question in this problem set, we will first illustrate how to calculate the various required values for a single sample, and then we will perform batch calculations to perform the calculations for the entire dataset at once. We will import an excel file with our data using VESIcal and create a BatchFile object that allows VESIcal to perform calcuations. We will also create a pandas DataFrame object called data\_values, and we will add newly calculated values to this object as we perform each calculation.

#### **About this notebook**

This notebook uses VESIcal to compute solubility curves, numpy for some math, pandas to handle dataframes, and matplotlib to plot. Pickle is used to "pickle" (save) computed values to memory and read them back in such that the computations do not need to be run each time the script is run (e.g., if it is desired to only update the plots).

If the MagmaSat model is desired (the default model in VESIcal), the ENKI thermoengine must also be installed on your machine to run this notebook. That is a bit cumbersome, so you may choose to only install VESIcal (without ENKI thermoengine, which is a separate install), which will allow you to use any model within VESIcal except for MagmaSat. In that case, we recommend chaging the <code>model</code> variable defined in 0.1 below from "MagmaSat" to "laconoMarziano".

#### Step 1. Set up the notebook

#### 1a. Import the necessary Python libraries

```
In [1]: # import the VESIcal library
import VESIcal as v

# import the matplotlib library to perform plotting and numpy library
import matplotlib.pyplot as plt
import numpy as np
import pandas as pd
import pickle
```

/opt/anaconda3/lib/python3.9/site-packages/numdifftools/extrapolatio n.py:10: DeprecationWarning: Please use `convolve1d` from the `scipy.ndimage` namespace, the `scipy.ndimage.filters` namespace is deprecated.

```
from scipy.ndimage.filters import convolve1d
/opt/anaconda3/lib/python3.9/site-packages/numdifftools/multicomplex.
py:35: DeprecationWarning: `finfo.machar` is deprecated (NumPy 1.22)
_TINY = np.finfo(float).machar.tiny
```

#### 1b. Import Data and Define Notebook Settings

```
In [2]: # import the Kilauea xlsx file as a VESIcal BatchFile object that VESI
data = v.BatchFile('Wieser_Kilauea_Data.xlsx', sheet_name="VESIcal")

# Let's also save the data as a pandas DataFrame object in order to bu
data_values = data.get_data()

# pull out a single composition to perform calculations on just that s
# pass asSampleClass=True to return a VESIcal Sample object that we ca
sample_LL8_613b = data.get_sample_composition("LL8_613b", asSampleClas

# choose which model to use for all VESIcal solubility calculations.
model = "MagmaSat"

# If desired, display the entire data file (remove # in front of code
# It is highly recommended to do this whenever importing a file to che
# data.get_data()

# If desired, display the composition of sample LL8_613b (remove # in
# sample_LL8_613b.get_composition()
```

/opt/anaconda3/lib/python3.9/site-packages/VESIcal/batchfile.py:165:
RuntimeWarning: No Label column given, so column 'Sample Name' was ch
osen for you. To choose your own, set label='<column-name>'.
 data = self.try\_set\_index(data, label)

# Step 2. Calculate saturation pressures for the melt inclusions based on the H<sub>2</sub>O and CO<sub>2</sub> concentrations of the glasses, using VESIcal

#### 2a. Single Sample

Calculate and print the saturation pressure for sample K99 using the MagmaSat model (the default in VESIcal). If another model is desired, pass <code>model="desiredmodelhere"</code> to the <code>calculate\_saturation\_pressure()</code> function call. We will use 1200 °C, as the temperature for all samples. If temperature values were given in the xlsx file, we could use a unique temperature for each sample by passing the name of the column (e.g.,

"Temperature") as the value for the temperature argument. The saturation pressure will be returned in bars.

#### 2b. Batch Calculation (all samples)

Calculate and print the saturation pressure for all Kilauea samples using the MagmaSat model (the default in VESIcal). If another model is desired, pass model="desiredmodelhere" to the calculate\_saturation\_pressure() function call. We will use a value of 1200 °C for the temperature. If temperature values were given in the xlsx file, we could use a unique temperature for each sample by passing the name of the column (e.g., "Temperature") as the value for the temperature argument. The saturation pressures will be returned in bars as a column named "SaturationP\_bars\_VESIcal" in a new data table (pandas DataFrame).

Finally, save add the data calculated here to our data\_files DataFrame.

The MagmaSat model can take a couple of minutes to run this calculation. To speed things up, we have calculated the saturation pressures ahead of time. The code block below will pull in that pre-calculated data in the form of a pickle file. If desired, you may uncomment the second code block below to perform the calculation yourself. You can also use another model within VESIcal such as the JaconoMarziano model.

```
.....
In [5]:
        This code will pull values already computed and saved into a pickle fi
        with open('pickle/satPs.pickle', 'rb') as handle:
            satPs = pickle.load(handle)
        data_values["SaturationP_bars_melt_only"] = satPs["SaturationP_bars_VE
        .....
        Uncomment the code below if you want to calculate the values on your d
        values if you want to change any of the parameters, of course. This wi
        file "satPs.pickle" with your newly calculated values.
        # # Perform the calculation on the BatchFile "data"
        # satPs = data.calculate_saturation_pressure(temperature=1200, model=m
        # # If desired, Print just the calculated saturation pressures
        # # print(satPs["SaturationP_bars_VESIcal"])
        # # Save our newly calculated pressures to the data_values DataFrame
        # data_values["SaturationP_bars_melt_only"] = satPs["SaturationP_bars]
        # # Pickle the calculated values to import later if so desired
        # with open('pickle/satPs.pickle', 'wb') as handle:
              pickle.dump(satPs, handle)
```

Out[5]: '\nUncomment the code below if you want to calculate the values on yo ur own. You must recalculate\nvalues if you want to change any of the parameters, of course. This will also overwrite the pickle\nfile "sat Ps.pickle" with your newly calculated values.\n'

# Step 3. Calculate the density of the melt as represented by the glass compositions using DensityX (lacovino & Till, 2019)

The DensityX model can be imported separately or used within VESIcal. Here we will use the one that is already inside of the VESIcal library.

#### 3a. Single Sample

Use the built-in function calculate\_liquid\_density to calculate the liquid density of sample LL8\_613b. We will use the temperature value of 1200 °C and the saturation pressure calculated in question 1 above. Density values are returned in units of g/L.

```
In [6]: liq_density_LL8_613b = v.calculate_liquid_density(sample=sample_LL8_61
liq_density_LL8_613b
```

Out[6]: 2716.081

#### 3b. Batch Calculation (all samples)

Use the built-in function <code>calculate\_liquid\_density</code> on the BatchFile object just created. As with Step 1, we will use 1200 ° C for the temperature for all samples. Use the saturation pressures calculated in Question 1 above as a unique pressure for each sample by passing the "SaturationP\_bars\_VESIcal" column from the <code>satPs</code> variable created above. Density values are returned in units of <code>g/L</code>.

```
In [7]: # Create a VESIcal BatchFile from our new data_values that contains ou
    satPs = v.BatchFile_from_DataFrame(data_values)

liq_densities = satPs.calculate_liquid_density(temperature=1200, press

# If desired, print just the calculated liquid densities
    # print(liq_densities["Density_liq_VESIcal"])

# Save our new values to the data_values DataFrame
    data_values["Density_liq_VESIcal"] = liq_densities["Density_liq_VESIcal"]
```

# Step 4. Calculate the density of the CO<sub>2</sub> in the bubbles using the equation to convert the diad separation into density

Here we will run through a simplified calculation using the empiracle regression from Fall et al. (2011):

$$\rho = -0.030314551\Delta^3 + 9.432834797\Delta^2 - 977.9384933\Delta + 33780.38242$$

Where  $\rho$  is the density and  $\Delta$  is the separation distance between the two peaks of the Fermi diad in cm<sup>-1</sup>. The python3 program <u>DiadFit (Wieser and DeVitre, 2024)</u> (https://www.jvolcanica.org/ojs/index.php/volcanica/article/view/252) can be used to process Raman spectroscopy data and provide a fit to measured peaks and correct for instrument drift. Wieser and DeVitre (2024) provided the necessary values of correction factor, regression gradient, and regression intercept that allow us to calculate CO<sub>2</sub> densities with their corrections. We'll create a second function to solve:

$$\rho = \Delta \times Corr \times Regr_{gradient} \times Regr_{intercept}$$

Where  $\rho$  is again the density,  $\Delta$  is again the Fermi diad separation, Corr is the correction factor,  $Regr_{gradient}$  is the gradient of the regression through their data, and  $Rerg_{intercept}$  is the intercept of the regression through their data.

In the dataset from Kilauea that we are using here, the separation distance between the diad peaks has already been calculated, so we will use the  $\Delta$  values from the xslx file under the column titled "CO2 Fermi Diad".

#### 4a. Single Sample

Let's write a function to solve the equation given above for  $CO_2$  vapor density,  $\rho$ .

```
rho = (-0.030314551 * diad_separation**3 +
            9.432834797 * diad_separation**2 -
            977.9384933 * diad_separation +
            33780.38242)
     return rho
def CO2_vapor_density_Wieser(diad_separation, correction_factor, regr_
     A function to calculate the density, rho, of CO2 vapor given the
     cm-1 and correction factors from Raman data from Wieser and DeVit
     Parameters
     diad_separation:
                        float
        The Fermi diad separation in cm-1.
      correction factor:
                           float
         Correction factor determined for the instrument used to take
         unique to each sample.
      regr_gradient:
                       float
         Gradient of the regression line through the standards used du
      regr_intercept:
                        float
         The intercept of the regression line through the standards us
      Returns
      float
         Vapor density of CO2, rho, in units of g/cm3
     rho = diad_separation * correction_factor * regr_gradient + regr_
     return rho
```

Now, let's get the diad separation value for sample LL8\_613b and use our function to calculate the vapor density, rho. We'll use the Wieser and Devitre (2024) equation to go with their data.

```
In [9]: # Get the diad separation and correction factor values from our data f
LL8_613b_diad_separation = data_values.loc["LL8_613b"]["Fermi diad sep
LL8_613b_correction_factor = data_values.loc["LL8_613b"]["Correction F

# The gradient and intercept of the regression of standards for these
regr_gradient = 0.321699687828446
regr_intercept = -32.9954729484350

# Use our function to calculate the vapor density, rho
rho_LL8_613b = C02_vapor_density_Wieser(LL8_613b_diad_separation, LL8_
# Print the pulled values and calculated vapor density, in units of g/
print("Diad separation for sample LL8_613b = " + str(LL8_613b_diad_separation)
print("Correction factor for sample LL8_613b = " + str(LL8_613b_correction)
print("The C02 bubble vapor density for sample LL8_613b = " + str(rho_
```

Diad separation for sample LL8\_613b = 102.616121121121Correction factor for sample LL8\_613b = 1.00017797800926The CO2 bubble vapor density for sample LL8\_613b = 0.021976516641970534

#### 4b. Batch Calculation (all samples)

Let's loop over the function we created above to solve for  $CO_2$  vapor density,  $\rho$ , in all of our samples. We will use a for loop to perform the calculation on each row of our data\_values object that we created in Step 0.

### Step 5. Calculate the concentration of CO<sub>2</sub> in the bubble (in ppm) using:

$$[CO_2]^{VB} = 10^4 \times \frac{\rho_{CO_2} V_{VB}}{\rho_{molt} V_{melt}}$$

where  $V_{VB}$  and  $V_{melt}$  are the volume of the vapor bubble and the melt phase of the inclusion, respectively, and  $\rho_{melt}$  is the density of the silicate melt.

The Kilauea data provide vapor and melt volumes within each inclusion in terms of the ratio,  $V_{ratio}$  of the volume of the vapor bubble over the volume of the silicate melt. We can rewrite the above equation as:

$$[CO_2]^{VB} = 10^4 \times V_{ratio} \times \frac{\rho_{CO_2}}{\rho_{melt}}$$

#### 5a. Single Sample

Let's write a function to solve the equation given above for  $CO_2$  concentration in the vapor bubble,  $\left[CO_2\right]^{VB}$ .

```
In [11]: def CO2_concentration_bubble(CO2_vapor_density, melt_density, volume_r
              A function to calculate the concentration of CO2 in a vapor bubbl
              in the bubble and of the silicate melt and the volumes of the bub
              Parameters
              CO2 vapor density:
                                   float
                 Vapor density of CO2, rho, in units of g/cm3
             melt density:
                             float
                 Density of the silicate melt, in units of g/L. This will need
                 to match the units on the CO2_vapor_density, but we use g/L as
                 is returned by VESIcal.
             volume ratio:
                             float
                 The ratio between the volume of the vapor and the volume of th
                 inclusion.
               Returns
               float
                  The concentration of CO2 in the vapor bubble, in units of ppm
             # translate melt density from g/L (output of VESIcal) to g/cm3 (ne
             melt_density_g_cm = melt_density / 1000.0
             CO2 conc = 10**4 * volume ratio * CO2 vapor density / melt density
             return CO2 conc
         # Get the ratio of vapor to melt volume in the MI, as reported in the
```

# In [12]: # Get the ratio of vapor to melt volume in the MI, as reported in the volume\_ratio = data\_values.loc["LL8\_613b"]["VolBubble\_VolMelt"] C02\_ppm\_LL8\_613b = C02\_concentration\_bubble(rho\_LL8\_613b, liq\_density\_ C02\_ppm\_LL8\_613b

Out[12]: 220.35858304847918

#### 5b. Batch Calculation (all samples)

Let's loop over the function we created above to solve for CO<sub>2</sub> concentration in ppm in all of our samples. We will run a for loop over the data\_values object that we created in Step 0 and have been adding data to throughout.

### Step 6. Calculate the total amount of CO<sub>2</sub> in the inclusion (in ppm):

$$[CO_2]^{Tot} = [CO_2]^{VB} + [CO_2]^{melt}$$

#### 6a. Single Sample

Let's write a function to solve the equation given above for  $CO_2$  concentration in the inclusion (bubble + melt),  $[CO_2]^{Tot}$ .

```
In [15]: # Get the concentrations of CO2 in the bubble and melt phase for one s
CO2_ppm_bubble = CO2_ppm_LL8_613b
CO2_ppm_melt = data_values.loc["LL8_613b"]["CO2_ppm_melt"]

CO2_total_LL8_613b = CO2_concentration_total(CO2_ppm_bubble, CO2_ppm_m
CO2_total_LL8_613b
```

Out[15]: 245.2121549611346

#### 6b. Batch Calculation (all samples)

Let's loop over the function we created above to solve for  $CO_2$  concentration in the inclusion in all of our samples. We will run a for loop over the data\_values object that we created in Step 0 and have been adding data to throughout.

### 6c. Let's compare CO<sub>2</sub> concentrations in the melt alone to those when the vapor bubble is included

We'll make a plot comparing the values. How significant is the  $CO_2$  in the bubble in terms of the amount of  $CO_2$  in the inclusion as a whole?

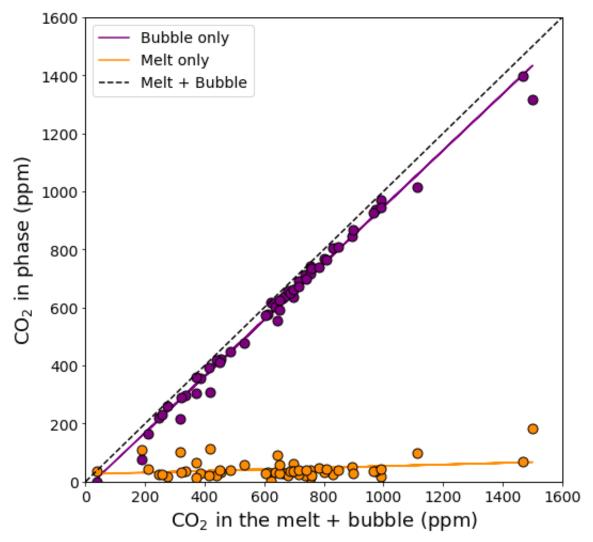

```
In [17]: # create a figure and axes with matplotlib
fig, ax = plt.subplots(figsize=(8,8))
ax.set_xlim(0,1600)

# define x and y values to plot
x = data_values["C02_ppm_total"] # C02 in the melt alone
y1 = data_values["C02_ppm_bubble"]
y2 = data_values["C02_ppm_melt"]

x_11 = np.linspace(0,1600)

# calculate linear fits for each data grouping
coef1 = np.polyfit(x,y1,1)
```

```
poly1d_fn1 = np.poly1d(coef1)
coef2 = np.polyfit(x,y2,1)
poly1d_fn2 = np.poly1d(coef2)
# add axis titles
ax.set_xlabel(r"$C0_2$ in the melt + bubble (ppm)")
ax.set ylabel(r"$CO 2$ in phase (ppm)")
# add linear fits to the plot
ax.plot(x, poly1d_fn1(x), color="#800080", label="Bubble only")
ax.plot(x, poly1d_fn2(x), color="#FF8C03", label="Melt only")
# add data to the plot
ax.plot(x, y1, '.', color="#800080", markersize=18, mec="black")
ax.plot(x, y2, '.', color="#FF8C03", markersize=18, mec="black")
ax.plot(x_11, x_11, '--', color="black", label="Melt + Bubble")
plt.legend()
fig.savefig('KilaueaExercise_Figure1.png', dpi=400) # save the figur
plt.show()
```

### Step 7. Use the total volatile contents of the inclusions to calculate saturation pressures using VESIcal.

Compare these pressures to those you calculated in Step 1. What can you conclude about the importance of analyzing bubbles in melt inclusions?

#### 7a. Create a new VESIcal BatchFile

First, we'll create a new BatchFile for samples where we consider CO<sub>2</sub> in both the bubble and melt. VESIcal always assumes that the values under a column labeled "CO2" correspond to the CO<sub>2</sub> value to use in units of wt%. For the melt+bubble CO<sub>2</sub> batch file, we will copy the data\_values object, and then overwrite the "CO2" column with the CO<sub>2</sub> concentration in total inclusion that we calculated above.

```
In [18]: # VESIcal BatchFile with CO2 in melt+bubble combined
data_melt_plus_bubble = data_values
data_melt_plus_bubble["CO2"] = data_values["CO2_ppm_total"] / 10000
data_melt_plus_bubble = v.BatchFile_from_DataFrame(data_melt_plus_bubble)
```

#### 7b. Calculate saturation pressures

Now, let's calculate the saturation pressures for all samples using where our CO<sub>2</sub> value is that of the CO<sub>2</sub> in the melt+bubble.

The MagmaSat model can take a couple of minutes to run this calculation. If desired, you may comment out the code in the cell directly below and uncomment and execute the code in the following cell, which will import a pickle file with this calculation already performed. You can also use another model within VESIcal such as the IaconoMarziano model.

```
.....
In [19]:
         This code will pull values already computed and saved into a pickle fi
         with open('pickle/SatPs_melt_plus_bubble.pickle', 'rb') as handle:
             SatPs_melt_plus_bubble = pickle.load(handle)
         # add these values to our data values object
         data values["SaturationP bars melt plus bubble"] = SatPs melt plus bub
         .....
         Uncomment the code below if you want to calculate the values on your d
         values if you want to change any of the parameters, of course. This wi
         file "SatPs_melt_plus_bubble.pickle" with your newly calculated values
         0.000
         # SatPs melt plus bubble = data melt plus bubble.calculate saturation
         # # add these values to our data_values object
         # data_values["SaturationP_bars_melt_plus_bubble"] = SatPs_melt_plus_b
         # # pickle the calculated values to read back in later if so desired
         # with open('pickle/SatPs_melt_plus_bubble.pickle', 'wb') as handle:
               pickle.dump(SatPs melt plus bubble, handle)
```

Out[19]: '\nUncomment the code below if you want to calculate the values on yo ur own. You must recalculate\nvalues if you want to change any of the parameters, of course. This will also overwrite the pickle\nfile "Sat Ps\_melt\_plus\_bubble.pickle" with your newly calculated values.\n'

#### 7c. Plot up the data and compare

Let's plot saturation pressures calculated with only the melt CO<sub>2</sub>, only the bubble CO<sub>2</sub>, and the combined melt + bubble CO<sub>2</sub>.

```
In [20]: # create a figure and axes with matplotlib
fig, ax = plt.subplots(figsize=(8,8))
ax.set_xlim(0,1600)
ax.set_ylim(0,2200)

# define x and y values to plot
x = data_values["C02_ppm_total"] # C02 in the melt alone
y1 = data_values["SaturationP_bars_melt_plus_bubble"]
y2 = data_values["SaturationP_bars_melt_only"]
y3 = x-y2

# calculate linear fits for each data grouping
coef1 = np.polyfit(x,y1,1)
poly1d_fn1 = np.poly1d(coef1)
coef2 = np.polyfit(x,y2,1)
```

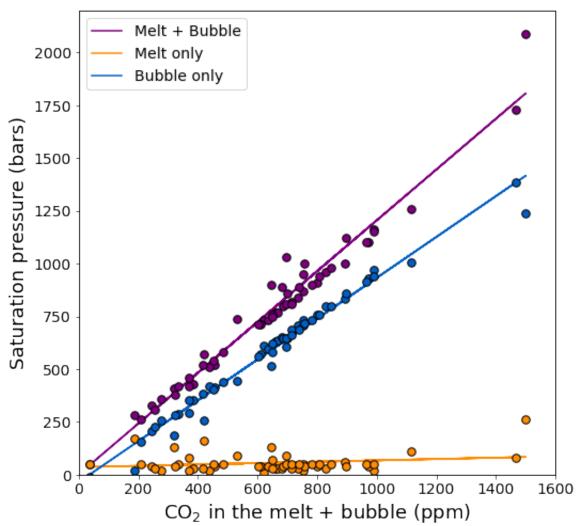

```
poly1d_fn2 = np.poly1d(coef2)
coef3 = np.polyfit(x,y3,1)
poly1d_fn3 = np.poly1d(coef3)

# add axis titles
ax.set_xlabel(r"$CO_2$ in the melt + bubble (ppm)")
ax.set_ylabel("Saturation pressure (bars)")

# add linear fits to the plot
ax.plot(x, poly1d_fn1(x), color="#800080", label="Melt + Bubble")
ax.plot(x, poly1d_fn2(x), color="#FF8C03", label="Melt only")
ax.plot(x, poly1d_fn3(x), color="#0160c6", label="Bubble only")

# add data to the plot
ax.plot(x, y1, '.', color="#800080", markersize=15, mec="black")
ax.plot(x, y2, '.', color="#FF8C03", markersize=15, mec="black")
ax.plot(x, y3, '.', color="#0160c6", markersize=15, mec="black")
plt.legend()

fig.savefig('KilaueaExercise_Figure2.png', dpi=400)  # save the figur
plt.show()
```

### Step 8. Save all calculated data to an Excel or CSV file

You can compare your results with the answer key to this notebook, found in a CSV file called 'Kilauea\_Exercise\_KEY.csv'.

In [21]: data\_values.to\_excel("Kilauea\_Exercise\_output.xlsx")
 data\_values.to\_csv("Kilauea\_Exercise\_output.csv")
